			ART UNIT 2618	PAPER NUMBER
			MAIL DATE 10/02/2007	DELIVERY MODE PAPER

**Please find below and/or attached an Office communication concerning this application or proceeding.**

The time period for reply, if any, is set in the attached communication.

<b>Office Action Summary</b>	<b>Application No.</b> 10/737,118	<b>Applicant(s)</b> MATSUNAGA, YASUHIKO	
	<b>Examiner</b> Marceau Milord	<b>Art Unit</b> 2618	

**-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --**

**Period for Reply**

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

**Status**

- 1) ☒ Responsive to communication(s) filed on 18 July 2007.
- 2a) ☐ This action is **FINAL**.                      2b) ☒ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

**Disposition of Claims**

- 4) ☒ Claim(s) 1-46 is/are pending in the application.
- 4a) Of the above claim(s) \_\_\_\_\_ is/are withdrawn from consideration.
- 5) ☐ Claim(s) \_\_\_\_\_ is/are allowed.
- 6) ☒ Claim(s) 1,2,4,5,7,8,11,12,14,17,20,23,26-33 and 37-46 is/are rejected.
- 7) ☒ Claim(s) 3,6,9,10,13,15,16,24,25,30,35 and 36 is/are objected to.
- 8) ☐ Claim(s) \_\_\_\_\_ are subject to restriction and/or election requirement.

**Application Papers**

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☐ The drawing(s) filed on \_\_\_\_\_ is/are: a) ☐ accepted or b) ☐ objected to by the Examiner.  
Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).  
Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

**Priority under 35 U.S.C. § 119**

- 12) ☐ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☐ All    b) ☐ Some \*    c) ☐ None of:
1. ☐ Certified copies of the priority documents have been received.
2. ☐ Certified copies of the priority documents have been received in Application No. \_\_\_\_\_.
3. ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

\* See the attached detailed Office action for a list of the certified copies not received.

## DETAILED ACTION

### Claim Rejections - 35 USC § 103

1. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

2. Claims 1-2, 4-5, 7-8, 11-12, 14, 17, 20, 23, 26-29, 33, 37, 41-43, 46 are rejected under 35 U.S.C. 103(a) as being unpatentable over Takao et al (US Patent No 6871071 B2) in view of Andersson et al (US Patent No 6334047 B1).

Regarding claims 1-2, Takao et al discloses a radio resource management method (figs. 1-3) comprising the control steps of: detecting (32 or 31 of figs. 1 and 6) the occurrence of interference between service areas provided by plural radio base stations (21 or 22 of fig. 1 and fig. 6; col. 3, line 44- col. 4, line 16; col. 7, line 59- col. 8, line 33) and controlling (RNC of figs. 1 and 6) transmission power of a common control signal, which governs a scope of a service area that a radio base station forms for interference suppression (col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of controlling transmission power of a common control signal, which governs a scope of a service area that a radio base station forms, for interference suppression in response to said occurrence of interference between service areas provided by plural radio base stations; detecting the occurrence of interference based on radio link quality information notified from each of said radio base stations.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot

Art Unit: 2618

the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). It is clearly stated that the power control indicator controls the transmission power of a common control signal, which governs a scope of a service area that a radio base station forms for interference suppression (fig. 1; figs. 6-7). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claims 4-5, Takao et al discloses a radio resource apparatus (figs. 1-3) comprising: detecting (32 or 31 of figs. 1 and 6) the occurrence of interference between service areas provided by plural radio base stations (21 or 22 of fig. 1 and fig. 6; col. 3, line 44- col. 4, line 16; col. 7, line 59-col. 8, line 33) and controller for controlling (RNC of figs. 1 and 6) transmission power of a radio base station (21 and 22 of figs. 1 and 6; col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of controlling transmission power of a common control signal which governs a scope of a service area that a radio base

Art Unit: 2618

station forms for interference suppression in response to said occurrence of interference between service areas provided by plural radio base stations; wherein the occurrence of interference is detecting based on radio link quality information notified from each of said radio base stations.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment

Art Unit: 2618

factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). It is clearly stated that the power control indicator controls the transmission power of a common control signal, which governs a scope of a service area that a radio base station forms for interference suppression (fig. 1; figs. 6-7). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claims 7-8, Takao et al discloses a radio base station in a radio communication system (figs. 1, 3, 6), said radio communication system including plural radio base stations each which provides a service area and a radio resource management apparatus for managing radio resources of said radio base stations (21 or 22 of fig. 1 and fig. 6; col. 3, line 44- col. 4, line 16; col. 7, line 59- col. 8, line 33), comprising: means (32 or 31 of figs. 1 and 6) for measuring a radio link quality and then notifying a radio resource management apparatus of radio link quality information being a measurement result (col. 9, line 42- col. 10, line 55; col. 11, lines 4- 65; col. 13, lines 45- col. 14, line 29; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the features of a means for responding transmission power control issued from a radio resource management apparatus and

Art Unit: 2618

then controllably changing transmission power, of a common control signal, which governs a scope of service area that a radio base station forms, to suppress interference between service areas detected based on said measurement result in said radio resource management apparatus; wherein said notification means performs a notification operation at predetermined notification intervals.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot

Art Unit: 2618

the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). It is clearly stated that the power control indicator controls the transmission power of a common control signal, which governs a scope of a service area that a radio base station forms for interference suppression (fig. 1; figs. 6-7). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 11, Takao et al discloses a radio resource management method (figs. 1-3) comprising the steps of: detecting (32 or 31 of figs. 1 and 6) the occurrence of interference between service areas provided by plural radio base stations (21 or 22 of fig. 1 and fig. 6; col. 3, line 44- col. 4, line 16; col. 7, line 59- col. 8, line 33) and controlling (RNC of figs. 1 and 6) transmission power (col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of controlling transmission power of a common control signal, which governs a scope of a service area that a radio base

Art Unit: 2618

station forms, for interference suppression in response to said occurrence of interference between service areas provided by plural radio base stations; detecting the occurrence of interference based on radio link quality information notified from each of said radio base stations.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment

Art Unit: 2618

factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). It is clearly stated that the power control indicator controls the transmission power of a common control signal, which governs a scope of a service area that a radio base station forms for interference suppression (fig. 1; figs. 6-7). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 14, Takao et al discloses a radio base station (figs. 1, 3, 6; 21 or 22 of figs. 1, 3, 6), comprising a detector for detecting (32 or 31 of figs. 1 and 6) the occurrence of interference between service areas provided by plural radio base stations (21 or 22 of fig. 1 and fig. 6; col. 3, line 44- col. 4, line 16; col. 7, line 59-col. 8, line 33) and controller for controlling (RNC of figs. 1 and 6) transmission power (21 and 22 of figs. 1 and 6; col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of controlling transmission power of a common control signal which governs a scope of a service area that a radio base station forms, to suppress interference autonomously in response to said occurrence of interference between plural service areas.

Art Unit: 2618

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its

Art Unit: 2618

transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). It is clearly stated that the power control indicator controls the transmission power of a common control signal, which governs a scope of a service area that a radio base station forms for interference suppression (fig. 1; figs. 6-7). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 17, Takao et al discloses a radio resource method (figs. 1-3; 12 of figs. 1 and 3) comprising the steps of: receiving information of radio link qualities from plural radio terminals (32 or 31 of figs. 1 and 6; col. 3, line 44- col. 4, line 16; col. 7, line 59-col. 8, line 33) and controlling (RNC of figs. 1 and 6) a load, being a radio terminal accommodated in a radio base station (21 and 22 of figs. 1 and 6; col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the features of a radio link quality information including information on link utilization to a radio base station in communication with each of the radio terminals, and wherein the load distributed control is based on the sum of sets of the link utilization information collected from respective radio terminals for each radio base station.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly

Art Unit: 2618

changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible

Art Unit: 2618

by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 20, Takao et al discloses a radio resource method (figs. 1-3; 12 of figs. 1 and 3) comprising: a receiver for receiving information of radio link qualities from plural radio terminals (32 or 31 of figs. 1 and 6; col. 3, line 44- col. 4, line 16; col. 7, line 59-col. 8, line 33) wherein said radio link quality information includes information on link utilization to a radio base station, which is in communication with each of said radio terminals (col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the features of a controller for distributively controlling a load, being a radio terminal accommodated in a radio base station, based on the information of radio link qualities from plural radio terminals, said controller comprising means for distributively controlling a load based on the sum of sets of said link utilization information collected from respective radio terminals for each radio base station.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease

Art Unit: 2618

in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an

Art Unit: 2618

adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 23, Takao et al discloses a radio resource management method (figs. 1-3; 12 of figs. 1 and 3) comprising the steps of receiving information of radio link qualities from plural radio terminals (32 or 31 of figs. 1 and 6; col. 3, line 44- col. 4, line 16; col. 7, line 59-col. 8, line 33) and a controller for controlling power (RNC of figs. 1 and 6) of a radio base station (21 and 22 of figs. 1 and 6; col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of controlling transmission power of a radio bases station based on the information of radio link qualities from plural radio terminals.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6,

Art Unit: 2618

line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claims 26-28, Takao et al discloses a radio resource management apparatus (figs. 1-3; 12 of figs. 1 and 3) comprising: a receiver for receiving information of radio link qualities from plural radio terminals (32 or 31 of figs. 1 and 6; col. 3, line 44- col. 4, line 16; col. 7, line 59-col. 8, line 33) and controller for controlling (RNC of figs. 1 and 6) transmission

Art Unit: 2618

power of a radio base station (21 and 22 of figs. 1 and 6; col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of controlling transmission power of a radio base station based on the information of radio link qualities from plural radio base stations.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot

Art Unit: 2618

the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 29, Takao et al discloses a radio resource management method (figs. 1-3; 12 of figs. 1 and 3) comprising the steps of: receiving information of radio link qualities from plural radio terminals (32 or 31 of figs. 1 and 6; col. 3, line 44- col. 4, line 16; col. 7, line 59-col. 8, line 33) and controlling (RNC of figs. 1 and 6) changing a frequency used by a radio base station (21 and 22 of figs. 1 and 6; col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8-col. 20, line 45).

However, Takao et al does not specifically disclose the features of controllably changing a frequency used by a radio base station based on the information of radio link qualities from plural radio terminals.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its

Art Unit: 2618

transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 33, Takao et al discloses a radio terminal (figs. 1-3; 32 or 31 of figs. 1 and 3) comprising: means (21 or 22 of figs. 1 and 3) for measuring a radio link quality and then notifying a radio resource management apparatus (12 of figs. 1 and 3) of radio link quality information being the measurement result, the notifying means performing a notifying operation at predetermined notification intervals (col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the features of a means for responding distributed control indication for a load being a radio terminal accommodated in a radio base station, based on said radio link quality information, the distributed control indication being created from the radio resource management apparatus, and switching a radio base station to be connected.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a

Art Unit: 2618

desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to

Art Unit: 2618

apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 37, Takao et al discloses a computer readable program (figs. 1-3), that operably controls a radio resource management apparatus (12 of figs. 1 and 3) in a radio communication system (col. 3, line 44- col. 4, line 16; col. 8, line 33; col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of responding to occurrence of interference between service areas provided by plural radio base station and then controlling the transmission power of a common control signal, which governs a scope of service area that a radio base station forms to suppress the interference.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6,

Art Unit: 2618

line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). It is clearly stated that the power control indicator controls the transmission power of a common control signal, which governs a scope of a service area that a radio base station forms for interference suppression (fig. 1; figs. 6-7). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 41, Takao et al discloses a computer readable program (figs. 1-3), that operably controls a radio base station (21 or 22 of figs. 1 and 3) in a radio communication

Art Unit: 2618

system, said radio communication system including plural radio base stations each providing a service area and a radio resource management apparatus for managing radio resources of said radio base stations (col. 3, line 44- col. 4, line 16; col. 8, line 33), comprising the steps of: measuring (21 or 22 of figs. 1 and 3) a radio link quality and then notifying said radio resource management apparatus (12 of figs. 1 and 3) of radio link resource information being a measurement result (col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of responding to transmission power control produced from said radio resource management apparatus and thus controlling a change of transmission power of a common control signal, which governs a scope of service area that a radio base station forms, to suppress interference between service areas detected based on the measurement result in said radio resource management apparatus.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value

Art Unit: 2618

indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). It is clearly stated that the power control indicator controls the transmission power of a common control signal, which governs a scope of a service area that a radio base station forms for interference suppression (fig. 1; figs. 6-7). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Art Unit: 2618

Regarding claim 42, Takao et al discloses a computer readable program (figs. 1-3), that computer controls the operation of a radio base station (21 or 22 of figs. 1 and 3) in a radio communication system, said radio communication system including plural radio base stations (21 or 22 of figs. 1 and 3) each providing a service area and a radio resource management apparatus for managing radio resources of said radio base stations (col. 3, line 44- col. 4, line 16; col. 8, line 33; 21 or 22 of figs. 1 and 3; col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of responding to occurrence of interference between plural service areas and controlling transmission power, to suppress interference autonomously.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal

Art Unit: 2618

quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 43, Takao et al discloses a computer readable program (figs. 1-3) for executing the operation of a radio terminal by means of a computer, comprising the control step of distributively controlling a load, being a radio terminal accommodated in a radio base station (col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of controlling a load, based on information on radio link qualities notified from plural radio terminals, including the sum of sets link utilization information collected from radio terminals for each radio base station.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment

Art Unit: 2618

factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

Regarding claim 46, Takao et al discloses a computer readable program (figs. 1-3) for executing the operation of a radio terminal by means of a computer, comprising the steps of: measuring a radio link quality and notifying a radio resource management apparatus (12 of figs. 1 and 3) of the radio link quality information being the measurement result (col. 9, line 42- col. 10, line 55; col. 11, line 65; col. 19, line 8- col. 20, line 45).

However, Takao et al does not specifically disclose the steps of responding a distributed control indication of a load based on a radio link quality information including the sum of sets of link utilization information collected from radio terminals, said distribution control being created from the radio resource management apparatus, said load being a radio terminal accommodated in a radio base station, and thus switching a radio base station to be connected.

On the other hand, Andersson et al, from the same field of endeavor, discloses an efficient and effective power control in a mobile communications system that adapts to rapidly

Art Unit: 2618

changing radio transmission conditions in varying and often unpredictable situations. The value of a signal parameter detected from a signal received by a radio transceiver is compared with a desired signal parameter value, and a difference is determined. A transmit power control command is sent to the radio transceiver and may instruct, for example, an increase or decrease in the level of radio transmit power. Included with the transmit power control command is a power control indicator indicating whether a first or a second type of power control adjustment should be used by the radio transceiver depending upon the determined difference. A first value indicates that the first type of power control adjustment should be used; the second value indicates that the second type of power control adjustment should be used (col. 5, line 43-col. 6, line 30). Furthermore, Andersson shows in figure 4, a controlling entity that detects a signal quality parameter, such as carrier-to-interference ratio, of a signal received from a controlled radio where the detected signal quality parameter is compared to a desired signal quality parameter, e.g., a target CIR, and a difference is determined. A transmit power control command is sent to the radio transceiver to either raise, lower, or make no change to the transceiver's current transmit power (col. 8, line 23-col. 9, line 11). The base station detects at every time slot the carrier to interference ratio of the signal received from the mobile station. In addition, the value of the power control indicator is set according to the determined power control adjustment factor, procedure, or scheme. The set power control indicator value is sent along with the transmit power control command to the mobile station. The mobile station receives and detects the TPC command and power control indicator and makes the appropriate adjustment to its transmit power based thereon. The power control adjustment factors, procedures, or schemes, comparison thresholds, etc. may be optionally changed and updated in a memory of or accessible

Art Unit: 2618

by the appropriate mobile and base stations (figs. 3-4, fig. 8; col. 12, lines 25-52). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Andersson to the communication system of Takao in order to provide an adaptive power control technique that ensures a satisfactory quality of communication at a minimum level of interference.

#### Claim Rejections - 35 USC § 102

3. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

A person shall be entitled to a patent unless –

(e) the invention was described in a patent granted on an application for patent by another filed in the United States before the invention thereof by the applicant for patent, or on an international application by another who has fulfilled the requirements of paragraphs (1), (2), and (4) of section 371(c) of this title before the invention thereof by the applicant for patent.

The changes made to 35 U.S.C. 102(e) by the American Inventors Protection Act of 1999 (AIPA) and the Intellectual Property and High Technology Technical Amendments Act of 2002 do not apply when the reference is a U.S. patent resulting directly or indirectly from an international application filed before November 29, 2000. Therefore, the prior art date of the reference is determined under 35 U.S.C. 102(e) prior to the amendment by the AIPA (pre-AIPA 35 U.S.C. 102(e)).

Art Unit: 2618

4. Claims 31, 38-40, 44-45 are rejected under 35 U.S.C. 102(e) as being anticipated by Partain et al (US Patent No 7068607 B2).

Regarding claim 31, Partain et al discloses a radio resource management apparatus (figs. 1-3) comprising: controller (RNC of fig. 6; the radio network controller is responsible for radio resource management for the UTRAN application) for controllably changing a frequency used by a radio base station based on information on radio link qualities notified from plural radio terminals (fig. 1; col. 4, lines 9-20; col. 6, lines 1-33; col. 5, lines 23-36). Partain et al shows in figure 3, a bandwidth broker server that collects information from various load measurement proxies located at various points in the network. This information is used to determine the congestion state of various paths through the network (col. 6, lines 8-25). The bandwidth broker processes the on-demand admission requests for IP resources by using the results of load control measurements (abstract; col. 3, lines 46-65).

Regarding claim 38, Partain et al discloses a computer readable program, that operably controls a radio resource management apparatus in a radio communication system (figs. 1-3), comprising a control step of distributively controlling a load (RNC of fig. 6; the radio network controller is responsible for radio resource management for the UTRAN application), being a radio terminal accommodated by a radio base station based on information on radio link qualities notified from plural radio terminals (fig. 1; col. 4, lines 9-20; col. 6, lines 1-33; col. 5, lines 23-36). Partain et al shows in figure 3, a bandwidth broker server that collects information from various load measurement proxies located at various points in the network. This information is used to determine the congestion state of various paths through the network (col. 6, lines 8-25).

Art Unit: 2618

The bandwidth broker processes the on-demand admission requests for IP resources by using the results of load control measurements (abstract; col. 3, lines 46-65).

Regarding claim 39, Partain et al discloses a computer readable program, that operably controls a radio resource management apparatus in a radio communication system (figs. 1-3), comprising a control step of distributively controlling a load (RNC of fig. 6; the radio network controller is responsible for radio resource management for the UTRAN application), being a radio terminal accommodated by a radio base station based on information on radio link qualities notified from plural radio terminals (fig. 1; col. 4, lines 9-20; col. 6, lines 1-33; col. 5, lines 23-36). Partain et al shows in figure 3, a bandwidth broker server that collects information from various load measurement proxies located at various points in the network. This information is used to determine the congestion state of various paths through the network (col. 6, lines 8-25). The bandwidth broker processes the on-demand admission requests for IP resources by using the results of load control measurements (abstract; col. 3, lines 46-65).

Regarding claim 40, Partain et al discloses a computer readable program, that operably controls a radio resource management apparatus (figs. 1-3) in a radio communication system comprising a control step (RNC of fig. 6; the radio network controller is responsible for radio resource management for the UTRAN application) of controllably changing a frequency used by a radio base station (BTS of fig. 1) based on information on radio link qualities notified from plural radio terminals (fig. 1; col. 4, lines 9-20; col. 6, lines 1-33; col. 5, lines 23-36). Partain et al shows in figure 3, a bandwidth broker server that collects information from various load measurement proxies located at various points in the network. This information is used to determine the congestion state of various paths through the network (col. 6, lines 8-25). The

Art Unit: 2618

bandwidth broker processes the on-demand admission requests for IP resources by using the results of load control measurements (abstract; col. 3, lines 46-65).

Regarding claim 44, Partain et al discloses a computer readable program for executing a radio resource management apparatus (figs. 1-3) in a radio communication system by means of a computer, comprising the control step (RNC of fig. 6; the radio network controller is responsible for radio resource management for the UTRAN application) of controlling transmission power of a radio base station (BTS of fig. 1) based on information on radio link qualities notified from plural radio terminals (fig. 1; col. 4, lines 9-20; col. 6, lines 1-33; col. 5, lines 23-36). Partain et al shows in figure 3, a bandwidth broker server that collects information from various load measurement proxies located at various points in the network. This information is used to determine the congestion state of various paths through the network (col. 6, lines 8-25). The bandwidth broker processes the on-demand admission requests for IP resources by using the results of load control measurements (abstract; col. 3, lines 46-65).

Regarding claim 45, Partain et al discloses a computer readable program for executing a radio resource management apparatus (figs. 1-3) in a radio communication system, by means of a computer, comprising the control step (RNC of fig. 6; the radio network controller is responsible for radio resource management for the UTRAN application) of controllably changing a frequency used by a radio base station (BTS of fig. 1) based on information on radio link qualities notified from plural radio terminals (fig. 1; col. 4, lines 9-20; col. 6, lines 1-33; col. 5, lines 23-36). Partain et al shows in figure 3, a bandwidth broker server that collects information from various load measurement proxies located at various points in the network. This information is used to determine the congestion state of various paths through the network (col.

6, lines 8-25). The bandwidth broker processes the on-demand admission requests for IP resources by using the results of load control measurements (abstract; col. 3, lines 46-65).

Claim Rejections - 35 USC § 103

5. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

6. Claim 32 is rejected under 35 U.S.C. 103(a) as being unpatentable over Partain et al (US Patent No 7068607 B2) in view of Carlsson et al (US Patent No 6167240).

Partain et al discloses everything claimed as explained in claim 31, except the features a control means control means that controls the frequency of a radio base station based on an interference amount being an average value of reception levels from neighboring radio base stations of the same frequency as the frequency used by an interested radio base station.

However, Carlsson et al also discloses a system and a method to reduce interference in a cellular communication system including at least one controlling arrangement communicating with a number of base stations, each of which serves a cell, and a number of mobile stations controlled by the base stations. Each base station includes a detecting device for detecting

Art Unit: 2618

interfering signals from one or more mobile stations controlled by other base stations. The base stations also include an alarm-activating device for activating the transmission of an alarm signal if interference is detected. The controlling arrangement includes a device for requesting identification of all mobile station in the neighborhood of the interfered base station. A device is also provided for establishing which controls base station an interfering mobile station, and the base station controlling the interfering mobile station takes the appropriate action to reduce the interference level (col. 2, lines 23-60; col. 4, lines 4-40). Furthermore, Carlsson et al shows in figure 5, a detector is implemented called base station user detector and which is used for detecting the users. The interference detector detects interfering signals generated by mobile stations controlled by other base stations (col. 7, lines 16-57; fig. 10; col. 8, line 51- col. 9, line 11). It is clearly stated that the occurrence of interference is detected based on the radio link quality information notified from the base stations (col. 7, lines 28-49; col. 8, line 55- col. 9, line 11). Therefore, it would have been obvious to one of ordinary skill in the art at the time the invention was made to apply the technique of Carlsson to the communication system of Partrain in order to provide a detector device in a base station for the purpose of reducing interference in a cellular communication system.

#### Allowable Subject Matter

7. Claims 3, 6, 9-10, 13, 15-16, 24-25, 30, 35-36 are objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

***Response to Arguments***

8. Applicant's arguments with respect to claims 1-2, 4-5, 7-9, 11-12, 14, 17, 20, 23, 26-29, 33, 37, 41-43, 46 have been considered but are moot in view of the new ground(s) of rejection.

**Conclusion**

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Marceau Milord whose telephone number is 571-272-7853. The examiner can normally be reached on Monday-Thursday.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Matthew D. Anderson can be reached on 571-272-4177. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of an application may be obtained from the Patent Application Information Retrieval (PAIR) system. Status information for published applications may be obtained from either Private PAIR or Public PAIR. Status information for unpublished applications is available through Private PAIR only. For more information about the PAIR system, see <http://pair-direct.uspto.gov>. Should you have questions on access to the Private PAIR system, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative or access to the automated information system, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.
